Micropower, Single Supply Rail-to-Rail Output Instrumentation Amplifiers

FEATURES

- **Micropower: 95µA Supply Current Max**
- **Low Input Offset Voltage: 100µV Max**
- **Low Input Offset Voltage Drift: 0.5µV/°C Max**
- **Single Gain Set Resistor:**
  - **G = 1 to 1000 (LT1789-1)**
  - **G = 10 to 1000 (LT1789-10)**
- **Inputs Common Mode to V⁻**
- **Wide Supply Range: 2.2V to 36V Total Supply**
- CMRR at G = 10: 96dB Min
- Gain Error: G = 10, 0.25% Max
- Gain Nonlinearity: G = 10, 40ppm Max
- Input Bias Current: 40nA Max
- PSRR at G = 10: 100dB Min
- 1kHz Voltage Noise: 48nV/$\sqrt{Hz}$
- 0.1Hz to 10Hz Noise: 1.5µV$_{P-P}$

APPLICATIONS

- Portable Instrumentation
- Bridge Amplifiers
- Strain Gauge Amplifiers
- Thermocouple Amplifiers
- Differential to Single-Ended Converters
- Medical Instrumentation

DESCRIPTION

The LT®1789-1/LT1789-10 are micropower, precision instrumentation amplifiers that are optimized for single supply operation from 2.2V to 36V. The quiescent current is 95µA max, the inputs common mode to ground and the output swings within 110mV of ground. The gain is set with a single external resistor for a gain range of 1 to 1000 for the LT1789-1 and 10 to 1000 for the LT1789-10.
The high accuracy of the LT1789-1 (40ppm maximum nonlinearity and 0.25% max gain error) is unmatched by other micropower instrumentation amplifiers. The LT1789-10 maximizes both the input common mode range and dynamic output range when an amplification of 10 or greater is required, allowing precise signal processing where other instrumentation amplifiers fail to operate. The LT1789-1/LT1789-10 are laser trimmed for very low input offset voltage, low input offset voltage drift, high CMRR and high PSRR. The output can handle capacitive loads up to 400pF (LT1789-1), 1000pF (LT1789-10) in any gain configuration while the inputs are ESD protected up to 10kV (human body).

The LT1789-1/LT1789-10 are offered in the 8-pin SO package, requiring significantly less PC board area than discrete multi op amp and resistor designs.

## TYPICAL APPLICATION

0.5A to 4A Voltage Controlled Current Source

V_S = 3.3V TO 32V

$I_{LOAD} = \dfrac{V_{IN}}{R_{SENSE} \cdot 10}$

= 1A PER VOLT AS SHOWN

RISE TIME ≈ 250µs, 10% TO 90%,
1A TO 2A OUTPUT STEP INTO 0.25Ω LOAD

* ENSURE ADEQUATE POWER DISSIPATION CAPABILITY AT HIGHER VOLTAGES, CURRENTS AND DUTY CYCLES

ABSOLUTE MAXIMUM RATINGS

(Note 1)

Supply Voltage (V$^+$ to V$^-$)..36V
Input Differential Voltage 36V
Input Current (Note 3).. ±20mA
Output Short-Circuit Duration.......................... Indefinite
Operating Temperature Range ....−40°C to 85°C
Specified Temperature Range (Note 4)
    LT1789C-1, LT1789C-10......................−40°C to 85°C
    LT1789I-1, LT1789I-10 ....−40°C to 85°C
Storage Temperature Range ....−65°C to 150°C
Lead Temperature (Soldering, 10 sec).................300°C

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: Does not include the effect of the external gain resistor R_G.

Note 3: This parameter is not 100% tested.

Note 4: The LT1789C-1/ LT1789C-10 is guaranteed to meet specified performance from 0°C to 70°C and is designed, characterized and expected to meet these extended temperature limits, but is not tested at −40°C and 85°C. The LT1789I-1/ LT1789I-10 is guaranteed to meet the extended temperature limits.

Note 5: Hysteresis in offset voltage is created by package stress that differs depending on whether the IC was previously at a higher or lower temperature. Offset voltage hysteresis is always measured at 25°C, but the IC is cycled to 85°C I-grade (or 70°C C-grade) or −40°C I-grade (0°C C-grade) before successive measurement. 60% of the parts will pass the typical limit on the data sheet.

Note 6: V_S = 5V limits are guaranteed by correlation to V_S = 3V and V_S = ±15V tests.

Note 7: V_S = 3V limits are guaranteed by correlation to V_S = 5V and V_S = ±15V tests.

Note 8: This parameter is not tested at V_S = 3V on the LT1789-10 due to an increase in sensitivity to test system noise. Actual performance is expected to be similar to performance at V_S = 5V.

BLOCK DIAGRAM

Figure 1. Block Diagram

APPLICATIONS INFORMATION

Setting the Gain

The gain of the LT1789-1 and LT1789-10 is set by the value of resistor R_G, applied across pins 1 and 8. For the LT1789-1, the gain G will be:

$$G = 1 + 200k/R_G$$

and R_G can be calculated from the desired gain by

$$R_G = 200k/(G - 1)$$

For the LT1789-10, the gain G will be

$$G = 10 \bullet (1 + 200k/R_G)$$

and R_G can be calculated from the desired gain by

$$R_G = 200k/(0.1 \bullet G - 1)$$

For the lowest achievable gain, R_G may be set to infinity by leaving Pins 1 and 8 open.

Input and Output Offset Voltage

The offset voltage of the LT1789-1/LT1789-10 has two components: the output offset and the input offset. The total offset voltage referred to the input (RTI) is found by dividing the output offset by the programmed gain (G) and adding it to the input offset. At high gains the input offset voltage dominates, whereas at low gains the output offset voltage dominates. The total offset voltage is:

Total input offset voltage (RTI) = input offset + (output offset/G)

Total output offset voltage (RTO) = (input offset $\bullet$ G) + output offset

APPLICATIONS INFORMATION

Reference Terminal

The output voltage of the LT1789-1/LT1789-10 (Pin 6) is referenced to the voltage on the reference terminal (Pin 5). Resistance in series with the REF pin must be minimized for best common mode rejection. For example, a 22Ω resistance from the REF pin to ground will not only increase the gain error by 0.02% but will lower the CMRR to 80dB.

Output Offset Trimming

The LT1789-1/LT1789-10 is laser trimmed for low offset voltage so that no external offset trimming is required for most applications. In the event that the offset needs to be adjusted, the circuit in Figure 2 is an example of an optional offset adjust circuit. The op amp buffer provides a low impedance to the REF pin where resistance must be kept to a minimum for best CMRR and lowest gain error.

Input Bias Current Return Path

The low input bias current of the LT1789-1/LT1789-10 (19nA) and the high input impedance (1.6GΩ) allow the use of high impedance sources without introducing significant offset voltage errors, even when the full common mode range is required. However, a path must be provided for the input bias currents of both inputs when a purely differential signal is being amplified. Without this path the inputs will float high and exceed the input common mode range of the LT1789-1/LT1789-10, resulting in a saturated input stage. Figure 3 shows three examples of an input bias current path. The first example is of a purely differential signal source with a 10kΩ input current path to ground. Since the impedance of the signal source is low, only one resistor is needed. Two matching resistors are needed for higher impedance signal sources as shown in the second example. Balancing the input impedance improves both common mode rejection and DC offset. The need for input resistors is eliminated if a center tap is present as shown in the third example.

Figure 2. Optional Trimming of Output Offset Voltage

Figure 3. Providing an Input Common Mode Current Path

APPLICATIONS INFORMATION

Output Voltage vs Input Common Mode Voltage

All instrumentation amplifiers have limiting factors that can cause an output to be invalid (the output is not equal to the input differential voltage multiplied by the gain) even though the output appears to be operating in a linear region. Limiting factors such as input voltage range and output swing can be easily measured, however, there are also internal nodes that can limit. These internal nodes cannot be measured externally and can lead to erroneous output readings.

To ensure a valid output for a given input common mode voltage and input differential voltage, the following four limiting factors must be taken into consideration (refer to the block diagram):

1) The input voltage ranges of the input amplifiers A1 and A2.

2) The output swings of the input amplifiers A1 and A2 (internal nodes).

3) The input voltage range of the output amplifier A3 (internal node).

4) The output swing of the output amplifier A3.

These limits can be determined using the relationships below.

1) The input voltage range limits can be found in the electrical tables.

2) The output voltages of the input amplifiers A1 and A2 can be found by the following formulas:

$$V_{OUT} A1 = (V_D/2)(G)(R1/R2) + V_{CM} + 0.6V$$

$$V_{OUT} A2 = (-V_D/2)(G)(R1/R2) + V_{CM} + 0.6V$$

Where V_D is the input differential voltage and V_{CM} is the input common mode voltage.

The typical output swing limits for A1 and A2 can be found in the Output Swing vs Load Current typical performance curve, using R1 + R2 as the load resistance.

This limitation usually becomes dominant when gain is taken in the input stage and the common mode input voltage is close to either supply rail.

The LT1789-10 is less susceptible to this limiting factor because the gain is taken in the output stage.

3) The voltage on the inputs to the output amplifier A3 can be determined by the following formula:

$$V_{IN} A3 = (V_{OUT} A1 - V_{REF})(R2/(R1 + R2))$$

The input voltage range of A3 has the same input limits as the LT1789-1. This limiting factor is more prevalent with single supplies, where both the reference voltage and input common mode voltage are near V⁺. This is also more of a concern with the LT1789-10 because the ratio of R1:R2 is 1:10 instead of 1:1.

4) The output voltage swing limits are also found in the electrical tables.

The Output Voltage vs Input Common Mode Voltage typical performance curves show the regions of operation for the three supply voltages specified.

Single Supply Operation

There are usually two types of input signals that need to be processed; differential signals, like the output of a bridge or single ended signals, such as the output from a thermistor. Both signals require special consideration when operating with a single supply.

When processing differential signals , REF (Pin 5) must be brought above the negative supply (Pin 4) to allow the output to process both the positive and negative going input signal. The maximum output operating range is obtained by setting the voltage on the REF pin to half supply. This must be done with a low impedance source to minimize CMRR and gain errors.

For single ended input signals, the REF pin can be at the same potential as the negative supply provided the output of the instrumentation amplifier remains inside the specified operating range. This maximizes the output range, however the smallest input signal that can be processed is limited by the output swing to the negative supply.
